Chapter 3

Recursion

Data Structures and Algorithms

Dr. Nguyen Ho Man Rang
Faculty of Computer Science and Engineering
University of Technology, VNU-HCM

- **L.O.8.1** - Describe the basic components of recursive algorithms (functions).
- **L.O.8.2** - Draw trees to illustrate callings and the value of parameters passed to them for recursive algorithms.
- **L.O.8.3** - Give examples for recursive functions written in C/C++.
- **L.O.8.5** - Develop experiment (program) to compare the recursive and the iterative approach.
- **L.O.8.6** - Give examples to relate recursion to backtracking technique.

Recursion

Definition

Recursion is a **repetitive process** in which an algorithm **calls itself**.

- Direct : $A \rightarrow A$
- Indirect : $A \rightarrow B \rightarrow A$

Example

Factorial

$$Factorial(n) = \begin{cases} 1 & \text{if } n = 0 \\ n \times (n - 1) \times (n - 2) \times \dots \times 3 \times 2 \times 1 & \text{if } n > 0 \end{cases}$$

Using recursion:

$$Factorial(n) = \begin{cases} 1 & \text{if } n = 0 \\ n \times Factorial(n - 1) & \text{if } n > 0 \end{cases}$$

Basic components of recursive algorithms

Two main components of a Recursive Algorithm

- ① Base case (i.e. stopping case)
- ② General case (i.e. recursive case)

Recursion and the
basic components
of recursive
algorithms

Example

Factorial

$$Factorial(n) = \begin{cases} 1 & \text{if } n = 0 \quad \text{base case} \\ n \times Factorial(n - 1) & \text{if } n > 0 \quad \text{general case} \end{cases}$$

Factorial: Iterative Solution

Algorithm iterativeFactorial(n)

Calculates the factorial of a number using a loop.

Pre: n is the number to be raised factorially

Post: $n!$ is returned - result in `factoN`

$i = 1$

`factoN` = 1

while $i \leq n$ **do**

`factoN` = `factoN` * i

$i = i + 1$

end

return `factoN`

End iterativeFactorial

Factorial: Recursive Solution

Algorithm recursiveFactorial(n)

Calculates the factorial of a number using a recursion.

Pre: n is the number to be raised factorially

Post: $n!$ is returned

if $n = 0$ **then**

 | return 1

else

 | return $n * \text{recursiveFactorial}(n-1)$

end

End recursiveFactorial

implementation in
C/C++

Properties of recursion

Properties of all recursive algorithms

- A recursive algorithm solves the large problem by using its solution to a simpler sub-problem
- Eventually the sub-problem is simple enough that it can be solved without applying the algorithm to it recursively.
→ This is called the **base case**.

Designing recursive algorithms

The Design Methodology

Every recursive call must either **solve a part** of the problem or **reduce the size** of the problem.

Rules for designing a recursive algorithm

- 1 Determine the **base case** (stopping case).
- 2 Then determine the **general case** (recursive case).
- 3 **Combine** the base case and the general cases into an algorithm.

Limitations of Recursion

- A recursive algorithm generally runs **more slowly** than its nonrecursive implementation.
- BUT, the recursive solution **shorter** and **more understandable**.

Print List in Reverse

Algorithm printReverse(list)

Prints a linked list in reverse.

Pre: list has been built

Post: list printed in reverse

if *list is null* **then**

 | return

end

printReverse (list -> next)

print (list -> data)

End printReverse

Definition

$$\gcd(a, b) = \begin{cases} a & \text{if } b = 0 \\ b & \text{if } a = 0 \\ \gcd(b, a \bmod b) & \text{otherwise} \end{cases}$$

Example

$$\gcd(12, 18) = 6$$

$$\gcd(5, 20) = 5$$

Greatest Common Divisor

Algorithm gcd(a , b)

Calculates greatest common divisor using the Euclidean algorithm.

Pre: a and b are integers

Post: greatest common divisor returned

if $b = 0$ **then**

 return a

end

if $a = 0$ **then**

 return b

end

return gcd(b , $a \bmod b$)

End gcd

Fibonacci Numbers

Definition

$$Fibonacci(n) = \begin{cases} 0 & \text{if } n = 0 \\ 1 & \text{if } n = 1 \\ Fibonacci(n - 1) + Fibonacci(n - 2) & \text{otherwise} \end{cases}$$

Fibonacci Numbers

Result

0, 1, 1, 2, 3, 5, 8, 13, 21, 34, ...

Fibonacci Numbers

Algorithm fib(n)

Calculates the n^{th} Fibonacci number.

Pre: n is positive integer

Post: the n^{th} Fibonacci number returned

if $n = 0$ or $n = 1$ **then**

 return n

end

return fib($n-1$) + fib($n-2$)

End fib

Fibonacci Numbers

No	Calls	Time	No	Calls	Time

The Towers of Hanoi

Move disks from Source to Destination using Auxiliary:

- 1 Only one disk could be moved at a time.
- 2 A larger disk must never be stacked above a smaller one.
- 3 Only one auxiliary needle could be used for the intermediate storage of disks.

The Towers of Hanoi

Moved disc from pole 1 to pole 3.

The Towers of Hanoi

Moved disc from pole 1 to pole 2.

The Towers of Hanoi

Moved disc from pole 3 to pole 2.

The Towers of Hanoi

The Towers of Hanoi

Moved disc from pole 2 to pole 1.

The Towers of Hanoi

Moved disc from pole 2 to pole 3.

The Towers of Hanoi

Moved disc from pole 1 to pole 3.

The Towers of Hanoi

The Towers of Hanoi : General

Complexity

$$T(n) = 1 + 2T(n - 1)$$

The Towers of Hanoi

Complexity

$$T(n) = 1 + 2T(n-1)$$

$$\Rightarrow T(n) = 1 + 2 + 2^2 + \dots + 2^{n-1}$$

$$\Rightarrow T(n) = 2^n - 1$$

$$\Rightarrow T(n) = O(2^n)$$

- With 64 disks, total number of moves:
 $2^{64} - 1 \approx 2^4 \times 2^{60} \approx 2^4 \times 10^{18} = 1.6 \times 10^{19}$
- If one move takes 1s, 2^{64} moves take about 5×10^{11} years (500 billions years).

The Towers of Hanoi

Algorithm move(val disks <integer>, val source
 <character>, val destination <character>, val auxiliary
 <character>)

Move disks from source to destination.

Pre: disks is the number of disks to be moved

Post: steps for moves printed

print("Towers: ", disks, source, destination, auxiliary)

if *disks* = 1 **then**

 | print ("Move from", source, "to", destination)

else

 | move(disks - 1, source, auxiliary, destination)

 | move(1, source, destination, auxiliary)

 | move(disks - 1, auxiliary, destination, source)

end

return

End move

Eight Queens Problem

Place eight queens on the chess board in such a way that no queen can capture another.

Eight Queens Problem

Algorithm putQueen(ref board <array>, val r <integer>)

Place remaining queens safely from a row of a chess board.

Pre: board is nxn array representing a chess board

r is the row to place queens onwards

Post: all the remaining queens are safely placed on the board; or backtracking to the previous rows is required

Eight Queens Problem

```
for every column  $c$  on the same row  $r$  do  
  if cell  $r, c$  is safe then  
    place the next queen in cell  $r, c$   
    if  $r < n-1$  then  
      putQueen (board,  $r + 1$ )  
    else  
      output successful placement  
    end  
    remove the queen from cell  $r, c$   
  end  
end  
return  
End putQueen
```
